ACKNOWLEDGEMENTS

I wish to thank Professor Michael Ghil for advising and inspiring me in this work. Also Dr. Robert Vautard has been a great help in introducing me to this subject and providing me with data as well as material. I am most grateful to Dr. Cécile Penland's support, personally and professionally, through discussions and meetings. She also supplied me with some additional data crucial for this work. Thanks are also addressed to Professors Akio Arakawa and David Neelin for contributing with their extensive knowledge, and to Dr. Kingtse Mo for interesting discussions. Johan has stood by me in every imaginable way and has given me lots of useful advice concerning general physics and computing. This work has been supported partly by NASA Grant NAG5-713 and by NSF Grant ATM86-15424.

ABSTRACT OF THE THESIS

North Atlantic Weather Regimes:
A Synoptic Study of Phase Space

by

Anna Karin Orrhede

Master of Science in Atmospheric Sciences

University of California, Los Angeles, 1990

Professor Michael Ghil, Chair

In the phase space of weather, low-frequency variability (LFV) of the atmosphere can be captured in a large-scale subspace, where a trajectory connects consecutive large-scale weather maps, thus revealing flow changes and recurrence. Using this approach, Vautard (1989) applied the trajectory-speed minimization method (Vautard and Legras, 1988) to atmospheric data. From 37 winters of 700 mb geopotential height anomalies over the North Atlantic and the adjacent land masses, four persistent and recurrent weather patterns, interpreted as weather regimes, were discernable: a blocking regime, a zonal regime, a Greenland anticyclone regime and an Atlantic ridge regime.

In this study, we investigate these regimes further in terms of

maintenance and transitions. A regime survey unveils preferences regarding event durations and precursors for the onset or break of an event. The transition frequencies between regimes vary, and together with the transition times, suggest the existence of easier transition routes. These matters are more systematically studied using complete synoptic map sequences from a number of events. In the maintenance of an event, oscillations between different balancing forces are observed, in connection with recurring nonlinear interaction sequences. Also the transition routes seem to contain particular evolution sequences leading to the next quasi-stationary flow pattern.
